Chapter 5.4: Joint Distributions and Independence

Working with Multiple Random Variables

Joint Distributions

We often need to consider two random variables together for instance, we may consider

- the length and weight of a squirrel,
- the loudness and clarity of a speaker,
- the blood concentration of Protein A, B, and C and so on.

This means that we need a way to describe the probability of two variables *jointly*. We call the way the probability is simultaneously assigned the "joint distribution".

Joint distribution of discrete random variables

Discrete RVs

For several discrete random variable, the device typically used to specify probabilities is a *joint probability function*. The two-variable version of this is defined.

A joint probability function (joint pmf) for discrete random variables X and Y is a nonnegative function f(x,y), giving the probability that (simultaneously) X takes the values x and Y takes the values y. That is,

$$f(x,y) = P[X = x \text{ and } Y = y]$$

Properties of a valid joint pmf:

- $f(x,y) \in [0,1]$ for all x,y
- $\sum_{x,y} f(x,y) = 1$

Joint distribution of discrete random variables

Discrete RVs

So we have probability functions for X, probability functions for Y and now a probability function for X and Y together - that's a lot of fs floating around though! In order to be clear which function we refer to when we refer to " f", we also add some subscripts

Suppose X and Y are two discrete random variables.

- we may need to identify the joint probability function using $f_{XY}(x,y)$,
- we may need to identify the probability function of X by itself (aka the marginal probability function for X) using $f_X(x)$,
- we may need to identify the probability function of Y by itself (aka the marginal probability function for Y) using $f_Y(y)$

Joint pmf

Discrete RVs

For the discrete case, it is useful to give f(x, y) in a **table**.

Two bolt torques, cont'd

Recall the example of measure the bolt torques on the face plates of a heavy equipment component to the nearest integer. With

X = the next torque recorded for bolt 3

Y =the next torque recorded for bolt 4

Joint pmf

Discrete RVs

the joint probability function, f(x, y), is

y x	11	12	13	14	15	16	17	18	19	20
20	0	0	0	0	0	0	0	2/34	2/34	1/34
19	0	0	0	0	0	0	2/34	0	0	0
18	0	0	1/34	1/34	0	0	1/34	1/34	1/34	0
17	0	0	0	0	2/34	1/34	1/34	2/34	0	0
16	0	0	0	1/34	2/34	2/34	0	0	2/34	0
15	1/34	1/34	0	0	3/34	0	0	0	0	0
14	0	0	0	0	1/34	0	0	2/34	0	0
13	0	0	0	0	1/34	0	0	0	0	0

Calculate:

•
$$P[X = 14 \text{ and } Y = 19]$$

Discrete RVs

•
$$P[X = 18 \text{ and } Y = 17]$$

By summing up certain values of f(x,y), probabilities associated with X and Y with patterns of interest can be obtained.

Discrete RVs

Consider: $P(X \ge Y)$

y\x	11	12	13	14	15	16	17	18	19	20
20										
19										8
18										
17										
16										
15										
14										
13										

$$P(|X-Y| \leq 1)$$

Discrete RVs

y\x	11	12	13	14	15	16	17	18	19	20
20										
19										
18										<i>p</i> .
17										
16										407
15										
14										
13										

$$P(X = 17)$$

Discrete RVs

y\x	11	12	13	14	15	16	17	18	19	20
20										
19										
18										<i>p</i> .
17										
16										407
15										
14										
13										

Marginal Distribution

Marginal distributions

Discrete RVs

In a bivariate problem, one can add down columns in the (two-way) table of f(x, y) to get values for the probability function of X, $f_X(x)$ and across rows in the same table to get values for the probability distribution of Y, $f_Y(y)$.

The individual probability functions for discrete random variables X and Y with joint probability function f(x,y) are called **marginal probability functions**. They are obtained by summing f(x,y) values over all possible values of the other variable.

Connecting Joint and Marginal Distributions

Discrete RVs

Use: Joint to Marginal for Discrete RVs

Let X and Y be discrete random variables with joint probability function Then the marginal probability function for X can be found by:

$$f_X(x) = \sum_y f_{XY}(x,y)$$

and the marginal probability function for Y can be found by:

$$f_Y(y) = \sum_x f_{XY}(x,y)$$

`

Example: [Torques, cont'd]

Discrete RVs

Find the marginal probability functions for X and Y from the following joint pmf.

y\x	11	12	13	14	15	16	17	18	19	20
20	0	0	0	0	0	0	0			1/34
19	0	0	0	0	0	0	2/34	0	0	0
18	0	0	1/34	1/34	0	0	1/34	1/34	1/34	0
17	0	0	0	0	2/34	1/34	1/34	2/34	0	0
16	0	0		1/34	2/34	2/34	0		2/34	0
15	1/34			0	3/34	0	0	0	0	0
14	0	0	0	0	1/34	0	0	2/34	0	0
13	0	0	0	0	1/34	0	0	0	0	0

Getting marginal probability functions from joint probability functions begs the question whether the process can be reversed.

Discrete RVs

Can we find joint probability functions from marginal probability functions?

Conditional Distribution

Discrete RVs

Conditional Distribution

Conditional Distribution of Discrete Random Variables

When working with several random variables, it is often useful to think about what is expected of one of the variables, given the values assumed by all others.

For discrete random variables X and Y with joint probability function f(x,y), the **conditional probability function of** X **given** Y=y is a function of x

$$f_{X|Y}(x|y) = rac{f(x,y)}{f_Y(y)} = rac{f(x,y)}{\sum\limits_x f(x,y)}$$

and the **conditional probability function of** Y **given** X = x is a function of y

$$f_{Y|X}(y|x) = rac{f(x,y)}{f_X(x)} = rac{f(x,y)}{\sum\limits_y f(x,y)}.$$

Discrete RVs

Conditional Distribution

Example: [Torque, cont'd]

$y\x$	11	12	13	14	15	16	17	18	19	20
20	0	0	0	0	0	0	0	2/34	2/34	1/34
19	0	0	0	0	0	0	2/34	0	0	0
18	0	0	1/34	1/34	0	0	1/34	1/34	1/34	0
17	0	0	0	0	2/34	1/34	1/34	2/34	0	0
16	0	0	0	1/34	2/34	2/34	0	0	2/34	0
15	1/34	1/34	0	0	3/34	0	0	0	0	0
14	0	0	0	0	1/34	0	0	2/34	0	0
13	0	0	0	0	1/34	0	0	0	0	0

Find the following probabilities:

•
$$f_{Y|X}(20|18)$$

Example: [Torque, cont'd]

• $f_{Y|X}(y|15)$

Discrete RVs

Conditional Distribution

• $f_{Y|X}(y|20)$

• $f_{X|Y}(x|18)$

Independence

Let's start with an example. Look at the following joint probability distribution and the associated marginal probabilities.

Discrete RVs

3 $f_Y(y)$ $y \setminus x$ 0.08 0.08 0.04 0.20 0.16 0.16 0.08 0.400.16 0.16 0.08 0.400.40 $f_X(x)$ 0.400.201.00

Conditional Distribution

Independence

What do you notice?

Discrete random variables X and Y are **independent** if their joint distribution function f(x,y) is the product of their respective marginal probability functions. This is,

Discrete RVs

independence means that

Conditional Distribution

 $f(x,y) = f_X(x) f_Y(y) \qquad ext{for all } x,y.$

If this does not hold, then \boldsymbol{X} and \boldsymbol{Y} are **dependent**

Independence

Alternatively, discrete random variables X and Y are independent if for all x and y,

If X and \$Y\$ are not only independent but also have the same marginal distribution, then they are **independent** and identically distributed (iid).
